

## Case Study: Cashew Processing in Ghana

Collected by: Technoserve/Ghana

Written by: Tellus Institute

Three cashew nut processors in Ghana had problems with controlling the quality of their product. To process cashews, first the raw nut is steamed and shelled, then dried in industrial dryers. The processors use the shells of the cashew nuts as fuel for steaming. The dryers, however, were fueled by firewood harvested locally. When the cashew nut shells are burned for fuel, they emit black oil known as Cashew Nut Shell Liquid (CNSL), which has a variety of industrial uses. Unfortunately, these three processors are not equipped to capture this liquid.

**Figure 2: Cashews in their shells**

Using firewood for fuel sometimes caused a problem for the businesses since the smell of the wood smoke would stay in the kernels, resulting in an unusable product. Also, it was difficult to regulate the temperature of the dryers using firewood. If the temperature were too hot, the kernels would burn, again resulting in waste product. Thus the businesses wanted to find a new source of fuel to run their dryers.

The government in Ghana was subsidizing propane gas tanks as a fuel source as part of a program to reduce deforestation. For two of the businesses, the subsidized gas was less expensive than the fuelwood. For the third business, however, fuel wood was essentially free since the staff harvested trees from on site.

All three businesses opted to switch to propane to run their dryers. The most important criteria for the decision were the ability to control temperature and smoke. Reducing

waste cashews resulted in better profitability, even for the business whose fuel costs increased with propane.

		<b>Company A</b>	<b>Company B</b>	<b>Company C</b>
